## 1 Introduction

- Our Project is **OCR** or **Optical Character Recognition**, specifically using English Alphabets and Numbers. The Main idea of **OCR** is to convert hand-written or printed text into machine-encoded text, whether it's coming from a scanned document, or a printed photo. **OCR** can be used in a wide variety of Activities, like: Voucher Code Scanning, QR code reading and Scanning Foreign Languages.

## 2 Project Overview

- Our Project manages to implement and execute **OCR** in its very own unique way.
- The Program first takes the external data-set as an Image, and converts it into a **GRAY-SCALE** image.
- The program afterwards takes the another external Image that we want to Read or Recognize.
- The Program then starts dividing (Segmentation) the image horizontally and Vertically by rows and columns.
- The program starts Inserting the divided image into two arrays, and starts the process of Training and Testing.
- After Training and Testing has been successfully completed, we assign a number to each letter and number of the Data-Set.
- At the end of the Program we use the (**KNN**) Classifier to try and find the nearest neighbors to each letter and number.
- Finally the program prints the values of the inserted image into the console, after using the Dictionary to translate each number to it's corresponding Letter or Number.

## 3 Libraries

- The Following Libraries have been used and imported inside our project, in order for us to be able to use some predefined functions and variables.

### 3.1 Numpy

- NUMPY is a fundamental package in python, that we used because it provides multidimensional array objects, along with the ability to perform fast operations on arrays, including mathematical, logical, shape manipulation and sorting.

### 3.2 Cv2

- OPENCV (Cv2) is also a fundamental library in Python designed to solve computer vision problems. we used this library in order to be able to read external Images and convert them into Gray-Scale Images.

### 3.3 Sklearn

- sklearn.metrics (Confusion Matrix) is mainly used in python to evaluate the accuracy of a classification. We used this particular library to be able to generate a matrix that shows how many times a Number or Letter has been successfully identified and recognized, and how many times it was not identified correctly.

## 4 Functions

- The Following functions has been used in implementing our **OCR** program :

- 1- **imread()** - Read Image from External Source.
- 2- **cvtColor()** - Convert Image color (Gray-Scale - Color).
- 3- **hsplit()** - Horizontally Split the Image.
- 4- **vsplit()** - Vertically Split the Image.
- 5- **reshape()** - Give a new shape to the array without changing its data.
- 6- **arange()** - Assign Values to other objects.
- 7- **repeat()** - Repeat elements of an array.
- 8- **KNearest-neighbor()** - Finding the nearest neighbour.
- 9- **confusion-matrix()** - Create or Construct a matrix, after receiving both the Actual and the Predicted values as parameters after classification happens.

## 5 Classifier

- The Classifier we used in our project is the **KNN** classifier. The **k-nearest neighbors** algorithm is mainly used for classification, so it stores all available cases and classifies new cases based on a similarity between them.

## 6 Project Sequence

### 6.1 Acquire Data-set

- Data-set required is acquired in an image form, and then converted to a Gray-Scale Image.

### 6.2 Acquire To-Be-Detected Image

- The Image to be converted is read, and also converted to a Gray-Scale Image.

### 6.3 Segmentation

- Both Images are divided Horizontally and Vertically, to be able to extract the unique feature of each Letter and Number in the Data-set and the External Image.

## 6.4 Dividing To Arrays

- The Segmented parts are then added into two arrays.

## 6.5 Training and Testing

- The Arrays are used for Training and Testing, normally training should be more than testing, for example a 80:20 ratio.

## 6.6 Assigning Values

- Values from 0 to 35 are assigned to the Numbers (0-9) and Letters (A-z).

## 6.7 Classification

- The KNN Classifier works to try and find the closest match and the nearest neighbor to each number and letter.

## 6.8 Printing Output

- The Outut of the External Image is then printed in the console.

## 6.9 Confusion Matrix

- At the End a Confusion-Matrix has been constructed, so we could observe the success and failure of our project, by counting how many times a Number or Letter has been successfully recognized after classification.

## 6.10 Dictionary

- To be able to get the correct values of each number and letter, after assigning values from 0 to 35 to them, a small dictionary has been created, that matches each value to it's corresponding Number or Letter.
